⍰ SUPERSEDED (in part), 2026-07-27 — the candidate set “{k∈{0,1,2}}” (the count definition, “line 37/55”) is SUPERSEDED by [[Keeper_K952_CORRECTED_blind_pre_registration_the_THRESHOLD_formula_is_the_blin 07-27]] (Cal §104 catch: hard-coding {0,1,2} assumes k_min=3, the 3-vs-4 discriminator, foreclosing the 4-branch — the blind object must be the DERIVED threshold). The FORM criterion (so(5,2) involution, singleton hw, no free knobs, scale-invariant positivity) and the retrofitting flags REMAIN SUPPORTED (Cal ratified). Current view: K952.

Keeper K950 — BLIND pre-registration: what makes the contravariant form CORRECT, committed BEFORE the signature

The occupancy count reduces to the signature of a finite contravariant (Shapovalov) Hermitian form on ψ_k, k=0,1,2 (K949/prompt 27k). The one way to fudge it is to choose the form to yield 3. So — committed NOW, blind, before Lyra/Elie compute the signature — here is the criterion for “the correct form.” Whatever the form fixed by these rules returns IS b. Any deviation from these rules to reach a target count invalidates the result.

[PROGRAM: TEGMARK] Keeper, 2026-07-27. Rule 5 (target-innocent anchoring) made a committed artifact. I pre-register the CRITERION (what fixes the form); Lyra/Elie own the CONSTRUCTION and the number.

The form is FIXED by these structural inputs — no free knobs

1. The involution/real form is $SO_0(5,2)$’s — the actual automorphism group of D_IV^5. The contravariant Hermitian form must be contravariant with respect to the Cartan involution of the REAL form so(5,2) (equivalently, the c-conjugate/Hermitian form of the unitarizable-module theory for this real form). It may NOT be taken with respect to a compact form (so(7)), a different real form, or a convenient inner product chosen to yield 3. This is the single most load-bearing constraint — the real form is where target-innocence lives.
2. The highest weight is the Di spinor singleton’s actual hw — fixed by the physical identification “matter = the spinor singleton” (A2, F709), NOT adjusted per-rung or chosen to move the answer. The base spinor u_0 is the SO(5) Dirac ground spinor (F326), not a tuned vector.
3. The states are the explicit modes ψ_k = (z_1+iz_2)^k ⊗ u_0, k=0,1,2 (F326), with their given SO(5) content (k+½,½), dims 4,16,40 — not a reselected basis.
4. Normalization is the standard hw-vector normalization ⟨v_λ,v_λ⟩=1; the relative norms ‖ψ_k‖^2 then FOLLOW from the form — they are not independently set.
5. Any regularization required at a reduction point (e.g. the ν=0 degenerate point needing Gindikin-Γ / analytic continuation) is the STANDARD analytic continuation of the holomorphic-discrete-series form — a fixed prescription, NOT a tunable parameter. No free regularization knob.

The count, defined before the number

b = #{ k ∈ {0,1,2} : ‖ψ_k‖^2 > 0 in the form fixed above }. - ‖ψ_k‖^2 > 0 → normalizable → counts as a generation-mode. - ‖ψ_k‖^2 = 0 (a null vector / the form degenerates at that rung — a reduction point) → NOT a normalizable generation (it is the boundary of the unitary range) → does NOT count. - ‖ψ_k‖^2 < 0 (form indefinite there) → not unitary → does NOT count. - The total generation count = b (in the uniform singleton framing; do NOT add Grace’s A1 interior result — A1 is mass-operator cleanliness, a separate question, K948 reconciliation watch).

The E7 cross-check, same rules

Repeat the construction with E7/E_VII’s real form (e7(−25)) and its own singleton hw, its own sub-threshold rungs. Report E7’s count by the IDENTICAL prescription — do NOT assume 4. Uniformity requires the same rule, not a re-tuned one.

What INVALIDATES the result (retrofitting flags — reject the number if any occur)

- Choosing a different involution/real form, or a non-canonical inner product, to reach a target count.
- Adjusting the hw, the base spinor, the mode basis, or introducing a free regularization parameter.
- Counting a null/degenerate rung as a generation (or excluding a positive one) to hit 3.
- Excluding a rung by the observed generation count or by a circular filtration argument (the reduced-not-eliminated situation; Cal refused it, ratified K948).
- Using the banked electron's position (K880) as an input to the form rather than letting it fall out.

The accepted outcomes (all honest)

- b such that total = 3 → premise ELIMINATED, E7-by-data exclusion airtight (given E7 → 4 by the same rule).
- total = 4 (a sub-threshold rung survives that "shouldn't") → geometry forces 4; observed 3 becomes a data cut → a LIVE FALSIFICATION of "geometry forces 3," and we publish it.
- total < 3 → the singleton/threshold identification needs rethink; say so. Whichever the structurally-fixed form returns is the answer. The premise stays REDUCED until the signature is read.

— Keeper K950, 2026-07-27 [TEGMARK]. Blind: the correct contravariant form is fixed by (so(5,2) real-form involution + Di-singleton hw + explicit modes + standard normalization + fixed regularization); b = # positive-norm rungs among k=0,1,2; E7 by the identical rule; retrofitting flags listed; committed before the number.
