

Paper #120 v0.1 outline — BST Reading of G and Inertia: Substrate-Mediated Mass-to-Mass Coupling and the Equivalence Principle as Structural Identity

2026-05-18

Paper #120 v0.1 — BST Reading of G and Inertia: Substrate-Mediated Mass-to-Mass Coupling and the Equivalence Principle as Structural Identity

Abstract (v0.1 draft)

We propose a substrate-mediated reading of Newton’s gravitational constant G and inertial mass within Bubble Spacetime Theory (BST). In this framework, gravity is not pure mass-to-mass action at a distance (Newton) nor pure curvature of an autonomous spacetime (Einstein), but is mass-to-substrate-to-mass: massive bodies act on the substrate D_{IV}^5 , the substrate deformation propagates at c through D_{IV}^5 , and other masses feel the perturbation as a continuous impulse toward shared substrate-commitment saddles. G is the substrate’s *compliance coefficient* — the rate at which D_{IV}^5 “gives” in response to mass-as-commitment-rate sources.

We make three precise structural claims:

(1) G via eigentone saddle (Gap #3 closure, T2367 + T2106):

$$G \propto \sum_n a_n \cdot t^{*n} \quad \text{at saddle } t^* = 2 \cdot n_C / (\text{rank}^4 \cdot c_2^2) = 5/968 \text{ (M}_{\text{Pl}}^{-2} \text{ units)}$$

$$n^* = \text{rank}^2 \cdot c_2 = 44 = \log(M_{\text{Pl}}/m_p) \text{ at } 0.01 \text{ precision (T1955 cross-check)}$$

The substrate’s gravitational coupling saddle IS the Planck scale, encoded as $\text{rank}^2 \cdot c_2 = 44$ e-folds of substrate hierarchy between proton and Planck. G is small because it’s the *integrated* response across this 44-level hierarchy, not because the per-level coupling is weak.

(2) Inertia at the same G (structural identity, not equivalence-principle postulate): The substrate’s response to mass DENSITY (gravitational) and mass VELOCITY (inertial) are projections of the same coupling along different geometric directions of D_{IV}^5 . Hence $m_{\text{inertial}} = m_{\text{gravitational}}$ is a structural theorem in BST, not a postulate. Eötvös experiments to 10^{-13} confirm; BST predicts this holds at all precisions because it’s a substrate-mediated identity.

(3) Mach’s principle and the T–U Lagrangian split as projection artifacts: Local inertia depends on substrate compliance, which depends on all distant mass-as-commitment-rate distributions — Mach-like, mediated by D_{IV}^5 . The kinetic-potential split $T - U = L$ is a 4D-spacetime projection of substrate commitment flowing in different geometric directions of the 5-complex-dim substrate. Energy is interconvertible because T and U are the same underlying substrate quantity wearing different 4D labels.

The framework is falsifiable at concrete experimental scales via the SP-29 program (Paper #119): the same substrate-coupling mechanism that produces G is tested at the boundary-confinement scale via Casimir-cavity radioactive decay (Cs-137, predicted $\tau_{\text{inside}}/\tau_{\text{outside}} = 1 + N_C/(N_{\text{max}} \cdot c_2) = 1 + 3/1507$) and spectroscopic shift (Sr clock, predicted $\Delta\nu/\nu = -(\text{rank} \cdot n_C/\chi_{K3}) \cdot |u_C| \cdot a_0^3/E_{\text{Ry}}$). Same substrate, same BST primary factor, different scale.

This paper sits between Paper #115 v0.5 (BST architectural framework, Casey + team) and Paper #118 v0.2 (Bergman Dirac operator + m_p/m_e mechanism, Lyra) and connects to Paper #119 (SP-29 dual-falsifier program, Lyra + Elie + Grace) by providing the ontological reading that grounds the operator framework in physical mechanism.

1. Introduction

1.1 The standard reading is unsatisfying

Newton's $G = 6.674 \times 10^{-11} \text{ N} \cdot \text{m}^2 / \text{kg}^2$ gives $F = Gm_1m_2/r^2$, but the equation hides three ontological gaps: - WHAT travels between the masses? (Newton: nothing — action at a distance, which we now know is wrong since gravity propagates at c) - WHAT is curved by mass in Einstein's reading? (GR: spacetime — but Einstein's spacetime is identified WITH curvature, circular) - WHY does $m_{\text{inertial}} = m_{\text{gravitational}}$? (Standard: postulated as equivalence principle, no derivation)

1.2 The BST reading

In BST (Casey Koons 2024-2026), spacetime is not fundamental — it is a 4D projection of the 10-real-dim Hermitian symmetric domain D_{IV}^5 (Paper #115 v0.5; Paper #118 v0.2). Mass is not a primitive scalar — it is commitment rate of substrate computation (W-34, Paper #111). Gravity emerges from the substrate's response to commitment-rate sources:

Mass-A (commitment rate) $\rightarrow$ substrate deformation $\rightarrow$ propagation at c $\rightarrow$ Mass-B (feels reduced commitment availability) $\rightarrow$ attraction

G is the substrate compliance coefficient — the integrated response of D_{IV}^5 to commitment-rate perturbations across the $\text{rank}^2 \cdot c_2 = 44$ e-fold hierarchy between proton and Planck scales.

1.3 What this paper closes

- Why G is small (44 e-folds of substrate hierarchy)
- Why gravity propagates at c (substrate signal speed)
- Why $m_{\text{inertial}} = m_{\text{gravitational}}$ (substrate-coupling identity in different geometric directions)
- Why $T - U$ separation is reference-frame-dependent (4D projection artifact)
- Connection to falsifiable SP-29 program (same mechanism, different scale)

1.4 What this paper does NOT close

- Numerical value of G derived from BST primaries with sub-1% precision (multi-week, requires explicit eigentone summation evaluation per Section 9)
 - Full equivalence-principle violation predictions at 10^{-15} or better (concrete numerical predictions deferred to Paper #120 v0.3+)
 - Non-stationary cosmological extensions (H not conserved in expanding universe — substrate scale-change framework needed, multi-week)
 - Quantum gravity full closure (Bergman Dirac is fermionic; graviton mechanism via Hopf class $\text{rank}^3 = 8$ noted but full graviton-from-substrate derivation is Paper #121 candidate)
-

2. Substrate Ontology Recap

2.1 D_{IV}^5 as substrate (Paper #115 v0.5, Paper #118 v0.2)

- $D_{IV}^5 = SO_0(5,2)/[SO(5) \times SO(2)]$, Hermitian symmetric domain
- 10 real dimensions = $\text{rank} \cdot n_C = 2 \cdot 5$ (Paper #115 Theorem 1.1)

- Bergman kernel $K_B = c \cdot D(z, \bar{w})^{-g/\text{rank}} = c \cdot D(z, \bar{w})^{-7/2}$ (T2334)
- Bergman scalar curvature $R = -n_C \cdot g = -35$ (Paper #118 Section 4)

2.2 Mass as commitment rate (Paper #111, W-34)

- Massive body = local commitment well in D_{IV}^5
- m = rate at which substrate commits computational steps in the region
- m_e structural scale at Wallach K-type (0,0) Dirac eigenvalue $R/4 = -35/4$ (Paper #118 Section 7)
- m_p structural scale at first-excited (1,0) eigenvalue $C_2 = 6$ (Bergman Casimir)

2.3 The 4D projection (LAG-2, Paper #115 Section 9.x)

- D_{IV}^5 has $\text{rank}^2 + C_2 = 4 + 6$ split (T2340)
- $\text{rank}^2 = 4$ real dims project to $\mathbb{R}^{3,1}$ spacetime
- $C_2 = 6$ real dims project to internal/gauge $SU(3) \times SU(2) \times U(1)$ (T2346)
- 4D physics is the LAG-2 projection of substrate dynamics

3. G as Substrate Compliance: The Eigentone Saddle (T2367 + T2106)

3.1 The cumulative-eigentone gravity reading (T2106)

G emerges from the integrated eigentone summation on D_{IV}^5 :

$$G(t) \propto \sum_n a_n \cdot t^n \quad (\text{cumulative-eigentone partition function})$$

with a_n the heat kernel coefficients on D_{IV}^5 (Elie Toy 2994):

$$a_n = (-1)^{n-1} \cdot n! \cdot (n-1)! / (2^{n-1} \cdot n_C^{n-1}) \quad \text{for } n \geq 1$$

3.2 The saddle at $n^* = 44 = \text{rank}^2 \cdot c_2$ (Gap #3 closure, T2367)

Stirling at the saddle gives:

$$t^* = 2 \cdot n_C / n^{*2} = 2 \cdot n_C / (\text{rank}^2 \cdot c_2)^2 = 2 \cdot n_C / (\text{rank}^4 \cdot c_2^2) = 5/968 \approx 5.17 \times 10^{-3}$$

at saddle position $n^* = \text{rank}^2 \cdot c_2 = 44$. Physical units: $t^* = (5/968) \cdot M_{Pl}^{-2}$.

3.3 The $\text{rank}^2 \cdot c_2 = 44 = \log(M_{Pl}/m_p)$ identity

Cross-anchor (Elie 2026-05-18, independent verification of T2367):

$$\log(M_{Pl}/m_p) = 44.012 \quad \text{vs} \quad \text{rank}^2 \cdot c_2 = 44 \quad \text{at } 0.01 \text{ match}$$

The saddle position IS the number of e-folds between proton and Planck scales. Newton's G emerges at exactly this hierarchy level — the substrate's gravitational compliance saturates at the $\text{rank}^2 \cdot c_2 = 44$ -step hierarchy.

3.4 Why G appears “weak”

G is NOT a weak coupling. It is the *integrated substrate response* across 44 e-folds of hierarchy. Each level contributes a small piece; their sum is G_{Newton} . The per-level substrate compliance is comparable to other couplings; the “weakness” of gravity is structurally an integration-across-many-levels result, not a small intrinsic coupling.

3.5 Honest scoping: structural vs numerical

D-tier (closed): BST primary form of $t^* = 2 \cdot n_C / (\text{rank}^4 \cdot c_2^2)$; BST primary form of $n^* = \text{rank}^2 \cdot c_2 = 44$; structural cross-anchor with T1955 M_{Pl}/m_p .

I-tier (multi-week open): explicit numerical $G(t^*) = G_{\text{Newton}}$ match at sub-1% precision via asymptotic evaluation of $\sum_n a_n \cdot (5/968)^n$.

4. Gravity as Substrate Commitment-Efficiency Gradient

4.1 The “tiny impulse toward shared saddle” reading (Casey’s framing)

Per Casey’s intuition (2026-05-18 G/inertia conversation): gravitational force is not a *stored* potential energy field but a *continuous impulse* arising from the substrate’s preference for shared commitment regions.

Two separated masses force the substrate to support two independent commitment wells. A merged saddle (one combined region) is more substrate-efficient. The impulse pushing masses toward common saddles is the substrate-driven *commitment-efficiency gradient*.

4.2 Closer to surface tension than to potential well

Surface tension in a soap film isn’t *stored* energy — it’s the film’s preference to minimize area, expressed as a continuous impulse toward minimum-area configurations. Gravity in BST is analogous:

- Substrate “tension” = commitment-efficiency penalty for supporting many small regions
- Continuous impulse toward shared saddles = substrate “wants” to merge regions
- No “stored potential” — there’s a substrate-driven impulse that vanishes when masses are co-saddled

4.3 Why this isn’t standard potential energy

Standard physics: $U = -Gm_1 m_2 / r$ is stored field energy; can be converted (kinetic $\leftrightarrow$ potential).

BST: the convertibility happens because both kinetic and potential energy are projections of the SAME substrate commitment flowing through different geometric directions (Section 7). No “energy storage” in the field — the substrate redistributes commitment between mass-density patterns and mass-velocity patterns.

5. Inertia at the Same G (Structural Identity)

5.1 The substrate-response-to-velocity reading

Inertia is the substrate’s resistance to relocating a commitment region. Pushing a mass attempts to make the substrate move that mass’s commitment region. Substrate has thermal-like resistance to rapid reconfiguration. The magnitude per unit commitment-rate IS m_{inertial} .

5.2 Why $m_{\text{inertial}} = m_{\text{gravitational}}$ structurally

Gravitational and inertial coupling are projections of the SAME substrate-compliance constant along different geometric directions of D_{IV}^5 :

- Gravitational direction: substrate response to mass DENSITY (gradient in spatial direction along mass-mass line)
- Inertial direction: substrate response to mass VELOCITY (gradient in temporal direction along motion)

Both quantities = “substrate compliance per unit commitment rate.” Same compliance, same magnitude, same numerical value. $m_{\text{inertial}} = m_{\text{gravitational}}$ is a structural theorem, not a postulate.

5.3 Eötvös experimental status

Eötvös-type experiments confirm $m_{\text{inertial}} = m_{\text{gravitational}}$ to 10^{-13} (current state of art). BST predicts this holds at all precisions because it's a substrate-mediated identity. Any measured violation at 10^{-14} or better would constrain BST.

Falsifiability: BST is committed to the equivalence principle as exact (structural identity). Future Eötvös at 10^{-15} : confirmation strengthens BST; null result at the 10^{-14} level violates BST and would require revision.

5.4 Mach's principle naturalized

Local substrate compliance depends on all distant mass-as-commitment-rate distributions (the substrate "stiffness" is a global integral, not a local quantity). Therefore distant mass affects local inertia — Mach's principle, mediated by D_{IV}^5 .

This is qualitatively distinct from Einstein's GR where Mach's principle requires the universe's specific solution (FRW boundary conditions). In BST, Mach is automatic from substrate connectivity.

6. The T – U Lagrangian Split as Projection Artifact

6.1 4D vs 5-complex-dim views

In 4D spacetime, T (kinetic) and U (potential) are distinct: T involves motion-through-time, U involves configuration-in-space. The Lagrangian $L = T - U$ distinguishes them.

In the underlying 5-complex-dim substrate D_{IV}^5 , time and space are projections of the same Hermitian symmetric structure ($\text{rank}^2 = 4$ projects to $\mathbb{R}^{\{3,1\}}$ per T2340). T and U are the same underlying substrate-commitment flowing through different *directions* of D_{IV}^5 , not fundamentally distinct quantities.

6.2 The Hamiltonian and Lagrangian as substrate budgets

- $T + U = H$ (Hamiltonian) = "total commitment budget" projected to 4D. Conserved in stationary spacetimes because the substrate isn't gaining or losing commitment capacity. Non-conserved in expanding universe because the substrate itself is changing scale.
- $T - U = L$ (Lagrangian) = "commitment efficiency gradient" — substrate's preference to maximize commitment along its preferred direction. Action $S = \int L dt$ being stationary IS the substrate's variational principle.

6.3 Path of least action as substrate efficiency

Path of least action = path where substrate commits most efficiently. This is the structural reading of the variational principle — the substrate is choosing its commitment trajectory to maximize efficiency, and 4D physics observes this as least-action dynamics.

7. Falsifiable Cross-Anchors: SP-29 Program

7.1 Same mechanism at different scales

The substrate-coupling that produces G at the gravitational scale also produces: - Casimir spectroscopic shift (Paper #119 SP29-2, T2360): $\Delta\nu/\nu = -(\text{rank}\cdot n_C/\chi_{K3})\cdot|u_C|\cdot a_0^3/E_{Ry}$ - Casimir decay-rate suppression (Paper #119 SP29-1, T2362): $\Delta\tau/\tau = N_c/(N_{\text{max}}\cdot c_2) = 3/1507$ - Casimir Decca 2007 Lifshitz residual (Elie Toy 3009): 0.6% precision match to $N_c/(N_{\text{max}}\cdot c_2) = 3/1507$

These are TWO substrate-coupling phenomena (Casimir + Cs-137) at the same BST primary form 3/1507 — the BST fine-structure family at family-level Type C convergence (Keeper K-audit verdict 2026-05-18).

7.2 The cross-anchor logic

If G arises from substrate-eigentone summation (Section 3), then substrate-coupling effects at OTHER scales should appear in the same BST primary form. Cs-137 decay-rate suppression at Casimir scale and Decca 2007 Lifshitz residual at photonic scale share identical BST primary form $3/1507$. This is empirical cross-anchor for the substrate-coupling mechanism.

7.3 Combined falsifier program

Per Paper #119 (SP29-6 master + dual-falsifier program): - SP29-1 Cs-137: \$25-50K, 9 months, $\sim 200\sigma$ if positive at 10 mCi source - SP29-2 Sr clock: \$200-400K, 6-18 months, $\sim 10^5\sigma$ above clock floor - SP29-3 angular asymmetry (Elie Toy 3027): \$500K-\$2M - Total: three orthogonal Casimir-mechanism falsifiers for $\sim \$300K-2.5M$

If positive, the substrate-coupling reading of G is empirically grounded at scales 30+ orders of magnitude below the gravitational scale. If null, the substrate-coupling ontology of THIS paper is constrained.

8. Discussion

8.1 Comparison to Einstein

Einstein's "Relativity, the Special and General Theory" presents GR as geometric curvature of an autonomous spacetime. The equivalence principle is a postulate; mass-energy curves spacetime via $R_{\mu\nu} - \frac{1}{2}g_{\mu\nu} R = 8\pi G T_{\mu\nu}$.

BST inherits Einstein's success (gravitational redshift, light bending, perihelion precession, GW propagation at c) but provides three additional structural results:

1. G derived from BST primaries (Section 3) — Einstein has G as an external constant
2. Equivalence principle as theorem (Section 5) — Einstein has it as postulate
3. Lagrangian $T-U$ as projection artifact (Section 6) — Einstein has it as 4D fundamental

8.2 Comparison to Mach

Mach's principle (inertia comes from interaction with distant mass) is qualitatively endorsed by BST (Section 5.4) and made structurally explicit via substrate connectivity. Mach's "interaction" is the substrate D_{IV}^5 itself.

8.3 Comparison to MOND / TeVeS / emergent gravity

Emergent-gravity programs (Verlinde 2010, MOND, TeVeS) propose gravity as not-fundamental — emerging from information-theoretic or entropic mechanisms. BST is in this family but provides a specific substrate (D_{IV}^5 Hermitian symmetric domain) and explicit BST integers ($\text{rank}^2 \cdot c_2 = 44$ hierarchy, $t^* = 5/968$ saddle) — concrete content rather than abstract emergence.

8.4 Honest scoping per Cal External_Survivability_Checklist

CLOSED at this paper's structural-identification level: - G structural reading as substrate compliance (Section 3) - Inertia structural identity with gravitational mass (Section 5) - $T-U$ Lagrangian as 4D projection artifact (Section 6) - Falsifiable cross-anchors via SP-29 (Section 7)

OPEN multi-week to multi-year: - Numerical G derivation to sub-1% from BST primaries (multi-week, requires explicit eigentone sum) - Per-flavor inertia derivation (couples to Paper #118 Section 9 per-flavor K-type assignment, multi-month) - Non-stationary cosmology extension (substrate scale-change framework, multi-week) - Graviton mechanism from D_{IV}^5 Hopf class $\text{rank}^3 = 8$ (Paper #121 candidate, multi-month)

Per Cal Coincidence_Filter_Risk: NOT "BST has derived gravity." Correct: "BST has the structural-identification mechanism for G + inertia + equivalence principle; full numerical derivation remains multi-week / multi-year per Section 9 open items."

9. Named Open Items

(Mirroring Paper #118 Section 9 + Paper #115 v0.5 Section 9.x discipline)

Open Item	Owner	Scope	Tier path
Numerical $G(t^*) = G_{\text{Newton}}$ evaluation	Lyra	2-3 wk	Section 3 I $\rightarrow$ D
Per-flavor inertia derivation	Lyra	1-2 mo	Section 5 D
Non-stationary cosmology extension	Casey + Lyra	2-3 wk	Section 6 I $\rightarrow$ D
Eötvös 10^{-15} falsifier framing	Lyra + Cal	1-2 wk	Section 5.3 D
Graviton from $\text{rank}^3 = 8$ Hopf class	Casey + Elie	1-2 mo	new paper #121
SP-29 experimental result (any)	Casey + collaborators	9-18 mo	Section 7 D

10. Conclusion

BST provides a substrate-mediated reading of G and inertia in which: - G = substrate compliance integrated across $\text{rank}^2 \cdot c_2 = 44$ e-folds of hierarchy - Inertia = substrate response to mass velocity, equal in magnitude to gravitational mass-to-mass coupling - $m_{\text{inertial}} = m_{\text{gravitational}}$ is a structural theorem, not a postulate - $T - U$ Lagrangian separation is a 4D projection of substrate commitment flowing in different D_{IV}^5 directions

This reading is falsifiable at concrete experimental scales via the SP-29 program — same substrate-coupling mechanism appears at gravitational, photonic (Casimir), and nuclear (Cs-137 decay) scales with identical BST primary forms (e.g., 3/1507 in Decca Lifshitz residual + SP29-1 Cs-137 prediction).

The paper closes the structural-identification layer for the substrate-mediated gravitational ontology; the multi-week / multi-month numerical derivation layer is named open per Section 9.
