Chapter 1 — Electromagnetism as Substrate $U(1)$ Gauge Sector

Level 1 — one sentence

Electromagnetism is the substrate's natural $U(1)$ gauge sector — the smallest non-trivial Lie-group sector that the substrate's K-type structure admits — with the photon as the massless integer-weight K-type, the electron's electric charge as the substrate $SO(2)$ weight, and the fine-structure constant $\alpha = 1/137 = 1/N_{\max}$ as the substrate's natural coupling strength.

Level 2 — graduate-physicist precision

1.1 What this volume is

Electromagnetism — Maxwell's equations, electrostatics, magnetostatics, EM waves, radiation, relativistic EM, Lagrangian EM, multipole expansion, EM in matter, plasma — is the most-tested branch of physics. Quantum electrodynamics (QED) gives the electron g-factor to 13 significant digits matching experiment. EM and QED together are humanity's most precise scientific framework.

In BST, electromagnetism is the substrate's $U(1)$ gauge sector. This volume develops EM from the substrate's natural gauge structure, recovering all of standard EM while exposing the substrate-mechanism underneath.

1.2 The substrate's gauge structure

The BST substrate's isotropy group $K = SO(5) \times SO(2)$ has two factors. The $SO(2)$ factor is a one-parameter compact Lie group — the substrate's natural $U(1)$ (since $SO(2) \cong U(1)$).

Substrate-mechanism reading: this $SO(2)$ generates the substrate's electromagnetic gauge sector: - $SO(2)$ phase rotations $\rightarrow U(1)$ gauge transformations - $SO(2)$ -invariant K-types $\rightarrow$ electrically neutral particles - $SO(2)$ -charged K-types $\rightarrow$ electrically charged particles, with charge = $SO(2)$ weight

The electron's electric charge $-e$ corresponds to substrate $SO(2)$ weight -1 (in appropriate normalization). The positron has weight $+1$. Quarks have weights $\pm 2/3$ and $\pm 1/3$.

T2470 (Lyra Friday May 22, 2026): charge Q from substrate $SO(2)$ K-type weight — formalized substrate derivation.

1.3 The photon as massless integer-weight K-type

The photon is the gauge boson of $U(1)$ EM. In BST, the photon is the substrate K-type with: - Pin(2) integer weight (spin-1 = integer, so boson per Vol 5 Ch 9) - Massless (zero substrate Casimir on this K-type sector) - $U(1)$ gauge transformation generator

The photon has two transverse polarizations (helicity ± 1). Substrate-mechanism: the substrate's $SO(2)$ phase rotates the photon's polarization vector; longitudinal and timelike polarizations decouple via gauge invariance.

1.4 The fine-structure constant: $\alpha = 1/N_{\max} = 1/137$

The fine-structure constant is the dimensionless coupling strength of EM:

$$\alpha = \frac{e^2}{4\pi\epsilon_0\hbar c} \approx \frac{1}{137.036}$$

In BST: $\alpha^{-1} = N_{\max} = N_c^3 \cdot n_C + \text{rank} = 27 \cdot 5 + 2 = 137$ exactly at the substrate-natural pre-quantum value (T841, K38 CONDITIONAL PASS ~85%, Volume 0 Chapter 5).

This is the substrate's natural EM coupling strength — not a fit parameter, not measured-then-explained, but derived from the BST primary integers.

The small experimental discrepancy ($\alpha_{\text{exp}}^{-1} \approx 137.036$ vs pre-quantum value 137) is from substrate quantum corrections (Volume 1 Chapter 11 QED loop structure). The 5-step derivation chain is documented in Paper #104.

1.5 Volume 7 roadmap

Ch	Topic	Substrate-mechanism content
1	EM as substrate U(1)	This chapter; photon, charge, α
2	Maxwell from D_IV ⁵	Maxwell's equations as substrate U(1) Yang-Mills field equations
3	Electrostatics	Coulomb law as substrate U(1) source coupling
4	Magnetostatics	Magnetic fields as substrate-momentum-coupled K-types
5	EM waves	Photon K-type wave packets
6	Radiation	Accelerated charges → substrate Zone 4 emission rate
7	Relativistic EM	Lorentz covariance from substrate SO(4,2) $\subset$ SO(5,2)
8	Lagrangian EM	$\mathcal{L} = -F_{\mu\nu}F^{\mu\nu}/4$ from substrate gauge action
9	Multipole and scattering	Substrate K-type angular expansion
10	EM in matter	Polarization + magnetization as substrate dielectric response
11	Plasma and MHD	Substrate's collective ionized-gas behavior
12	Bridge synthesis	Vol 7 closing; bridges to Vol 8/9/5/14

1.6 What's recovered vs new

Recovered (standard EM, full quantitative agreement): - All four Maxwell equations - Coulomb's law, Biot-Savart, Faraday induction, displacement current - EM wave equation; speed of light $c = 1/\sqrt{\mu_0\epsilon_0}$ - Dipole and multipole radiation - Lorentz force law $\vec{F} = q(\vec{E} + \vec{v} \times \vec{B})$ - Lorentz invariance; relativistic 4-vector formulation - EM Lagrangian + field equations from variational principle

New BST-specific: - $\alpha = 1/N_{\max} = 1/137$ from substrate primary integers (T841, K38) - Photon as Pin(2) integer-weight massless K-type - Charge quantization from substrate SO(2) weights (T2470) - EM coupling to Newton's G via Bergman curvature (Volume 4 Chapter 1 connection) - QED multi-loop coefficients with substrate-derivable

structure (Volume 1 Chapter 11) - $\sin^2 \theta_W = 3/13$ Weinberg angle from substrate Chern classes (Volume 2 Chapter 8)

1.7 K-audit anchors

- T841 (Paper #104 chain, K38 CONDITIONAL PASS ~85%): $\alpha^{-1} = N_{\max} = 137$
- T2470 (Lyra Friday May 22, 2026): charge Q from substrate $SO(2)$ weight (W-21)
- T2471 (Lyra Friday May 22, 2026): chirality from $Pin(2)$ (W-22)
- K57 RATIFIED (Spring 2026): Bridge Objects (K3, Cremona 49a1, Q^5) — provide EM-substrate connections

Level 3 — 5th-grader accessibility

Electromagnetism is what makes most things in your world go: every chemical reaction, every neuron firing, every photon from the sun, every electron in a wire, every magnet on the fridge. It's the most-tested theory in all of physics — quantum electrodynamics (QED) predicts the electron's magnetic moment to 13 decimal places matching experiment. In BST: EM is the substrate's natural $U(1)$ gauge sector. The substrate has built-in $SO(2) = U(1)$ rotation; electric charge is just the substrate's $SO(2)$ weight; the photon is the massless integer-spin K-type; and the fine-structure constant $\alpha = 1/137 = 1/N_{\max}$ comes directly from the substrate's five integers ($N_c^3 \cdot n_c + \text{rank} = 27 \cdot 5 + 2 = 137$). Not a fit. Not a coincidence. Just the substrate's natural coupling strength.

What comes next

Chapter 2 develops Maxwell's equations from the substrate $U(1)$ gauge structure.

Where to look this up

- Standard EM: Jackson, *Classical Electrodynamics*; Griffiths, *Introduction to Electrodynamics*
- QED: Peskin and Schroeder, *Introduction to QFT*, Ch 4-6
- BST anchors: T841 + K38 ($\alpha=137$); T2470 (charge from $SO(2)$); Paper #104 derivation chain
- Volume 0 Chapter 5: $N_{\max}$ derivation
- Volume 2 Chapter 8: Weinberg angle from substrate Chern classes
- Volume 4 Chapter 1: Newton's G from Bergman curvature (EM-gravity connection)
