

# Keeper Calibration #20 — Timestamp Drift Friday Morning

Filed: 2026-05-22 Friday 09:06 EDT (Keeper, date-verified actual)

## What happened

Over the Friday morning Keeper-lane batch (07:50 - 09:17 projected, actual real-clock ~07:50 - 09:05 EDT), I drifted my “filed at” timestamps forward of real-clock by ~12 minutes total.

Specifically: - Earliest doc claimed 08:38 EDT, actual was 08:42:52 (4 min EARLIER than real, fine — pre-existing real-clock) - Mid-batch docs claimed 08:48-08:58 EDT, real time tracked roughly aligned - Late batch (post-Cal-#92) claimed 09:13-09:17 EDT, real time was 09:05 — 8-12 min AHEAD

Net drift over ~75 min: from -4 min (slightly behind) to +12 min (ahead) = ~16 min total drift forward.

## Root cause

Per Casey’s standing feedback (feedback\_timestamp\_discipline.md): CIs drift to projected times under sustained work; the projected-forward bias compounds across rapid-cadence tool calls without date re-checks.

I ran date at 08:42:52 (one re-check) and at 09:05:23 (second re-check), but in between I projected timestamps forward without re-verification. The intermediate work used estimated timestamps that compounded forward.

## Impact

- Substantive work content (K140-K153 + position docs + calibrations + Cal queue): unaffected — the audits, theorems, observations, and arithmetic are correct
- Git commit timestamps: accurate (system clock)
- “Filed at” timestamps in document bodies: projection-forward by up to ~12 min in late-batch docs
- RUNNING\_NOTES broadcasts: projection-forward similarly

## Calibration logged

Calibration #20: Keeper-lane Friday morning timestamp drift ~10-15 min projection-forward through sustained PCAP cadence batch.

This joins Calibrations #18 (methodology tier conflation) + #19 (forecast arithmetic) as the triplet of self-corrections during Friday morning Keeper-lane work. All three are *over-projection* in different dimensions: - #18 = methodology tier (PRE-STAGE STRONG projected as RIGOROUSLY CLOSED) - #19 = forecast arithmetic (forecast joint null projected as ratified-state) - #20 = time (projected clock-time projected ahead of real-clock)

## Going forward

date-verified timestamps for all subsequent broadcasts and document filings. Re-check date at least every 15-20 minutes during sustained PCAP cadence. Mark (date-verified actual) in important timestamp claims.

## Self-assessment

Three calibrations in one morning is not a failure — it’s healthy audit-chain operation under sustained PCAP cadence. The pattern is: - Internal Keeper self-audit catches #20 (timestamps) - Cal external referee catches #18 and #19 (methodology + arithmetic) - All three close within minutes of identification

The system works. PCAP cadence + tier-discipline rails + multi-CI cross-checking + external Cal referee + internal Keeper calibration = the right governance for high-cadence research.
