Calibration candidate — Source-Verification Tier

The rule

A claim that rests on a specific value or statement from the literature — a classification entry, a tabulated invariant, the exact statement *or scope* of a cited theorem — must be tagged one of: - VERIFIED-CITED — the actual source text was checked/quoted *this session*. - RECALLED — stated from memory, even when the citation is known.

A load-bearing claim CANNOT advance past MATCHED on a RECALLED value. The label “sourced” (or “sourced, not guessed”) is reserved for VERIFIED-CITED. Knowing the citation is not the same as having checked it.

Why (the recurrence that forces a hard gate)

Two failures in two days, both on the *deepest-gate* claim, both the same mechanism: 1. FK genus (last week): the genus name flipped 3× in one day from relabeling-from-memory; pinned only after deriving from the multiplicity formula. Recorded as `feedback_pin_conventions_to_primary_sources`. 2. $\hat{B}_2$ tube count (today): Elie’s E1b cited Dlab–Ringel but stated the rule from memory and labeled it “sourced, not guessed” — and it was wrong: the simply-laced $\tilde{D}/\tilde{E}$ “non- $\tilde{A} \rightarrow 3$ tubes” theorem (≥ 5 vertices) was applied out of scope to the 3-vertex non-simply-laced $\hat{B}_2$ species. Cal #27 + the #407 audit caught it; Elie retracted cleanly.

Recording the lesson did not prevent recurrence within a day. A lesson is a soft norm; this needs a hard tier gate.

How to apply

- When a claim invokes “by [theorem / classification / table],” the asserter states whether the source text was checked this session. If not → RECALLED → the claim is capped at MATCHED until VERIFIED-CITED.
- Scope is part of the value. The failure mode today was not a wrong number recalled — it was a *correct theorem applied outside its hypotheses* ($\tilde{D}/\tilde{E}$ vs $\hat{B}_2$). So VERIFIED-CITED requires checking that the cited theorem’s hypotheses actually cover the case at hand, not just that the theorem exists.
- Especially binding on: Dynkin/classification data (tubular types, genus tables, Coxeter numbers), and any “standard theorem” invoked on a non-generic object (non-simply-laced, small rank, boundary cases).
- In-environment honesty: if the source cannot be opened here (e.g., a Memoir/monograph not extractable), the claim is RECALLED by default and stays MATCHED — exactly the disposition the $\hat{B}_2$ tube count now carries.

Disposition

Candidate. If ratified: it sits alongside Cal #27 (result-level forward-vs-identified) and Cal #29 (design-level) as the sourcing-level gate. It would have caught both recurrences at assertion time rather than at audit time.

— Keeper, 2026-05-28. The audit chain caught the miss; this is the structural fix so the *next* deepest-gate claim can't repeat it.
