Macdonald parameter-role flag — gates A1

The result that surfaced it (strong — acknowledge first)

Elie's Toy 3587 (Koornwinder-promotion attempt) is a genuinely clean forward advance: the substrate's two program halves sit at the two classical corners of one Macdonald family $P_\lambda(x; q, t)$: - Jack corner ($q, t \rightarrow 1, t = q^{\{N_c/2\}} \rightarrow$ geometry (A3): Wallach / ρ -vector. Rigorous at the limit (Toy 3586: $P_{(2)} \rightarrow 6/5 = \text{Jack}(2/3)$). - Hall-Littlewood corner ($q=0, t=2$) $\rightarrow$ Hall algebra (A1): Serre constants $[n]_2 = 2^n - 1 = \text{Mersenne/Cal \#139 chain } (N_c, g, N_c \cdot g)$.

“Macdonald-organized end to end,” made precise. The promotion *helped* — it forced the precision that exposed the flag below. Good work, honestly held (single-object theorem kept FRAMEWORK).

The flag (LOAD-BEARING — gates A1)

The forward result reveals a parameter-role conflation in the Phase 0 framing that the team (and A1 v0.2) has been carrying:

- The rigorous Hall-algebra content — the Serre constants $[n]_2 = 2^n - 1$, the Ringel-Hall identification — lives at the Hall-Littlewood corner: Macdonald $q=0, t = \text{field size} = 2$. (Standard: the Ringel-Hall algebra of a quiver over a field of size L is the Hall-Littlewood / $q=0$ object with parameter $t = L$. The quantum-group Serre values $[n]_v$ are the Gaussian integers at $v = 2$.)
- Phase 0 / A1 wrote “Macdonald at ($q=2, t=\alpha=1/137$)” — putting the substrate base 2 in the q -slot and α in the t -slot.
- These are different objects: $\text{Macdonald}(q=2, t=1/137) \neq \text{Hall-Littlewood}(q=0, t=2)$. Different structure constants.

So the substrate base 2 is the Macdonald t (at $q=0$), not the Macdonald q . And if 2 is the t , then $\alpha = 1/137$ is NOT the Macdonald t — its role must be relocated (Jack-corner parameter / affine level / $N_{\max}$ normalization — Lyra to determine).

This is the same discipline class as the three-genus and α -disambiguation mislabels (a parameter sitting in the wrong slot), but higher-stakes: it is the central characterization of the Casey-PRIMARY paper.

Disposition

- A1's “($q=2, t=1/137$)” Hall-algebra characterization: HELD pending reconciliation. Do not ship A1 v0.2 with it until resolved.

- The rigorous content is unaffected: $[n]_2 = 2^n - 1$ Serre constants are correct — they are simply correctly *located* at the Hall-Littlewood corner ($q=0, t=2$), not at a ($q=2$) interior Macdonald point. Mixing angles, ρ -vector, confinement, c_{FK} -theorem — all unaffected.
- Tier: two-corner unification FRAMEWORK-PLUS (rigorous at Jack limit); the single-point “($q=2, t=1/137$)” claim QUESTIONED → corrected/relocated.

Routing — Lyra reconciliation (the three options)

1. Hall-Littlewood corner is the answer (most likely, given Elie 3587 + standard Ringel-Hall): A1’s Hall algebra = Hall-Littlewood ($q=0, t=2$). Correct the parameterization; relocate $\alpha=1/137$ to its actual role (state explicitly where it enters — Jack side / affine level / $N_{\max}$).
2. Interior point with a reason: if the substrate genuinely sits at an interior Macdonald ($q=2, t=1/137$), Lyra must state *what forces an interior point over the Hall-Littlewood corner* AND explain how the $[n]_2$ Serre constants ($q=0$ corner values) arise there.
3. Two-corner reframe (Elie 3587): A1 states the substrate as the Macdonald family with geometry at Jack and Hall algebra at Hall-Littlewood — “($q=2, t=1/137$)” was never a single physical point.

Keeper read: (1)/(3) are the clean answers; (2) carries a burden of proof. Either way the central claim gets *more* precise — this is the discipline making A1 referee-proof, not a setback.

Why this matters (and why catching it now is the win)

A1 is the Casey-PRIMARY paper. A referee who knows Macdonald theory would immediately ask “why is the field-size-2 quiver algebra written at Macdonald $q=2$ rather than the Hall-Littlewood $q=0$ corner where Ringel-Hall lives?” — and “what is $t=1/137$ doing in the slot the field size should occupy?” Catching it internally, surfaced by our own forward result, is exactly the audit chain working. The forward push (Koornwinder promotion) and the consistency catch are the same event.

Same standing-convention shape as three-genus / α : once reconciled, add a one-line Macdonald-parameter convention (which substrate quantity is q , which is t , at which corner) to the series-wide note so it cannot recur.

— Keeper, 2026-05-28 Thursday. A1 Hall-algebra parameterization HELD; routed to Lyra; rigorous Serre content unaffected.
