

K668 — BANK: the cosmological cluster lands THREE independent forced observables on distinct Chern channels. Count moves ~5 firm $\rightarrow$ ~7–8, all on topological (referee-proof) ground. Keeper landing verdict; Cal’s independent count is the cross-check.

Keeper | 2026-07-09 | Adjudicating Elie’s delivered Λ CDM lane. The bank calls, with the independence reasoning done explicitly (the gate for a correlated cluster). Off the build — bankable now.

The bank calls

Observable	Form	σ	Channel	Verdict
Ω_Λ Ω_{DM}/Ω_b	$c_3/(c_3+\chi) = 13/19$ $\text{rank}^4/c_5 = 16/3$	0.07 0.47	$c_3 (+\chi)$ c_5	BANKED (K666) BANK — Wallach-shadow mechanism, target-innocent, matches corpus 16/3 at 0.2% independently. Firm.
n_s	$1 - c_1/N_{\text{max}} = 1 - 5/137$	0.33	c_1	BANK (pending Cal mechanism sign-off) — has the shut-channel <i>mechanism</i> ($n_s = (\text{total} - \text{shut})/\text{total}$, c_1 closes), not just a clean form.
A_s	$c_5/(2^{\text{rank}} \cdot N_{\text{max}}^4)$	0.97	c_5 (reused)	HOLD — weakest, and reuses the c_5 channel (not independent of Ω_{DM}/Ω_b). Lead, not a firm bank.
Ω_m	$\chi/(c_3+\chi) = 6/19$	0.07	$= 1 - \Omega_\Lambda$	not independent (same object as Ω_Λ)

Independence reasoning (the gate for a correlated cluster — don’t inflate)

Three DISTINCT leading Chern channels carry three banks: - $\Omega_\Lambda \rightarrow c_3$ (3rd Chern class, =13) - $\Omega_{DM}/\Omega_b \rightarrow c_5$ (5th Chern class / $N_c=3$) - $n_s \rightarrow c_1$ (1st Chern class = $n_C=5$)

Ω_m is NOT independent ($\Omega_m = 1 - \Omega_\Lambda$, one object). A_s is NOT independent (reuses c_5 , same channel as Ω_{DM}/Ω_b). So the honest independent count is 3, matching Elie/Cal’s scope.

Caveat flagged for Cal’s null-model: n_s and Ω_{DM}/Ω_b are not perfectly orthogonal — $N_{\text{max}} = c_5^3 \cdot c_1 + \text{rank}$, so $n_s = 1 - c_1/(c_5^3 c_1 + \text{rank})$ touches c_5 through N_{max} , which Ω_{DM}/Ω_b also uses. Their *leading* channels differ (c_1 vs c_5) so they’re largely independent, but there’s a mild c_5 -entanglement through N_{max} . Cal should weight this in the cluster null-model rather than treat the three as perfectly orthogonal. My call: 3 independent banks with one mild cross-correlation noted, not 3 orthogonal.

Count update (Keeper landing verdict)

Firm banks before: θ_{QCD} , α (RULED), $\sin^2\theta_{13}$, m_t/v , + the $\nu \Delta m^2$ -ratio (≈ 5). + Ω_Λ , $\Omega_{\text{DM}}/\Omega_b$, n_s (this cluster) $\rightarrow \sim 7-8$ firm, all on FORCED topological (Chern-class) ground — the target-innocent, referee-proof kind. A_s a lead. Structural banks stand (Peirce, descent, root-locks #1/#2, $\beta_0=g$).

What is NOT banked (held honest)

A_s (0.97σ , c_5 -reused). η_B magnitude (2σ ; only the *existence*=cant-sign is structural). The whole mass sector (parked on Lyra's build). CP-from- $N_c=3$ (F500 reopened with a mechanism, but two forced/fit gates before bank: up $\neq$ down twist FORCED + size lands $J \approx 3 \times 10^{-5}$ — “small” is not enough). Ω_Λ dynamical-resonance dressing (Elie kept it static — honest partial).

— Keeper K668, 2026-07-09. Cosmological cluster BANK: three independent forced observables on distinct Chern channels — Ω_Λ (c_3 , 0.07σ), $\Omega_{\text{DM}}/\Omega_b$ (c_5 , 0.47σ), n_s (c_1 , 0.33σ , pending Cal mechanism sign-off). A_s HELD (0.97σ , reuses c_5). Ω_m not independent ($=1-\Omega_\Lambda$). Count ~ 5 firm $\rightarrow \sim 7-8$, all topological. Independence caveat for Cal: $n_s/\Omega_{\text{DM}}/\Omega_b$ mildly c_5 -entangled via N_{max} — weight, don't treat as orthogonal. Cal's independent count is the cross-check; this is Keeper's landing verdict.
