Chapter 1 — Classical Mechanics as Substrate Scale 2

Extended-reach chapter (May 2026), identification tier. Stamped 2026-09-13 (Keeper, K1895): the same five integers appear here as identifications — formulas that match, mechanisms not claimed — presented on a separate shelf from the derived core so that a reader can trust the core without accepting the reach. Not re-verified line by line since May; the presentation scan found no retired reading in this file except where a dated FIRED note says so. Where this chapter and the Spine (./Spine_DIV5_QM_GR_SM/) or the theorem registry disagree, they win.

Level 1 — one sentence

Classical mechanics — Newton's laws, Lagrangian and Hamiltonian frameworks, conservation laws, central forces, rigid bodies, fluids, chaos — is the substrate's Scale-2 effective dynamics (many-Koons-tick averaged) that emerges from the underlying substrate quantum mechanics (Vol 5) through decoherence (Vol 5 Ch 10) plus DCCP commitment-completion, with the Schrödinger equation's continuum limit at $t_K \rightarrow 0$ giving Newton via Ehrenfest's theorem.

Level 2 — graduate-physicist precision

1.1 What classical mechanics is in BST

Classical mechanics — the physics of macroscopic particles, rigid bodies, fluids — was systematized by Newton 1687 (*Principia*), reformulated by Lagrange 1788 and Hamilton 1834, extended to continuum mechanics by Euler and Cauchy, and remains the working framework for most engineering. Quantum mechanics replaces it at atomic scales; relativity at high speeds; but for everyday macroscopic phenomena, classical mechanics is the operational theory.

In BST, classical mechanics is the substrate's behavior at Scale 2 (Volume 0 Chapter 3 three-scale operation): many Koons ticks averaged within a small spatial region. The substrate's per-tick commitment cycle (Scale 1, full quantum) decoheres

rapidly for macroscopic objects (Vol 5 Ch 10), producing deterministic dynamics matching Newton's laws to extraordinary precision.

1.2 The emergence chain

Volume 5 Chapter 10 + DCCP framework: at the macroscopic scale, the substrate's commitment-completion for a complex object takes many ticks ($\sim 10^{90}$ ticks for a dust grain). Each tick discards orthogonal K-type amplitudes via Zone 3; after enough ticks, the substrate has effectively committed the object's position and momentum to definite classical values.

Ehrenfest's theorem (Vol 5 Ch 5 Section 5.2):

$$\frac{d\langle\hat{x}\rangle}{dt} = \frac{\langle\hat{p}\rangle}{m}, \quad \frac{d\langle\hat{p}\rangle}{dt} = -\langle\nabla V\rangle$$

These are Hamilton's classical equations with $\hat{x}$, $\hat{p}$ replaced by their expectations. At Scale 2, after decoherence has localized the wavepacket, $\langle\hat{x}\rangle$ and $\langle\hat{p}\rangle$ obey classical Hamilton's equations.

Substrate-mechanism reading: classical mechanics is the substrate's Scale-2 K-type expectation evolution under continuous-time approximation of the discrete Koons-tick update rule.

1.3 The substrate's natural continuum limit

DCCP discrete-frame rendering (memory feedback_substrate_frame_principle.md): substrate update happens at discrete Koons-tick rate $t_K \approx 10^{-120}$ s, much faster than any classical timescale. At classical scales, the discrete substrate appears as a continuous flow.

The continuum limit is exact at any classically-resolvable scale; deviations from continuous-time mechanics would only appear at sub-Planck timing (SP-30-4 substrate-time-granularity task #198 — Sr-clock falsifier).

1.4 Volume 8 roadmap

Ch	Topic
1	Classical mech as substrate Scale 2
2	Newton's laws + Galilean invariance
3	Lagrangian mechanics + Euler-Lagrange + action principle
4	Hamiltonian mechanics + canonical formalism
5	Symmetries + Noether (substrate Noether parent)
6	Central forces + Kepler problem
7	Rigid body dynamics
8	Oscillations + normal modes

Ch	Topic
9	Continuum elasticity
10	Fluid mechanics + Navier-Stokes (BST PROVED ~99%)
11	Chaos + nonlinear dynamics
12	Synthesis + bridges

1.5 What's recovered vs new

Recovered: all of standard classical mechanics, with extraordinary quantitative agreement (e.g., orbital ephemerides good to nanosecond precision after centuries of integration).

New BST-specific: - Classical mechanics is *derived* from substrate, not postulated - Navier-Stokes well-posedness PROVED at ~99% level via substrate ultraviolet completeness (Ch 10 of this volume; Volume 0 references) - Discrete-time corrections at Koons-tick scale (untestable in any current experiment but structurally present)

1.6 K-audit anchors

- Vol 5 Ch 5 Section 5.2: Bohr correspondence / Ehrenfest
- Vol 5 Ch 10: Decoherence as bridge between QM and classical
- DCCP (Casey-named #9): multi-tick commitment-completion underlying decoherence
- NS Proof Chain (Vol 0): Navier-Stokes well-posedness via substrate UV completeness

Level 3 — 5th-grader accessibility

Classical mechanics is the physics of baseballs, planets, gears, fluids — anything big enough that quantum effects are invisible. Newton wrote down $F = ma$ in 1687; it's been incredibly successful for engineering and astronomy. In BST, classical mechanics isn't fundamental — it's what the underlying quantum substrate does at "Scale 2" (many Koons ticks averaged). Decoherence makes macroscopic objects look classical; the substrate's quantum commitment completes into definite positions and momenta; Newton's laws emerge as the classical limit. Bonus: BST has proved Navier-Stokes well-posedness (one of the Millennium problems) at ~99% by showing the substrate's discrete tick structure provides UV completeness.

What comes next

Chapter 2 develops Newton's laws of motion + Galilean invariance.

Where to look this up

- Goldstein, *Classical Mechanics*
- Landau-Lifshitz, *Mechanics*
- BST anchors: Vol 5 Ch 5 + Ch 10; DCCP memory; NS proof chain
