Chapter 8 — BaTiO₃ 137-Plane: BST's Signature Condensed-Matter Falsifier

Extended-reach chapter (May 2026), identification tier. Stamped 2026-09-13 (Keeper, K1895): the same five integers appear here as identifications — formulas that match, mechanisms not claimed — presented on a separate shelf from the derived core so that a reader can trust the core without accepting the reach. Not re-verified line by line since May; the presentation scan found no retired reading in this file except where a dated FIRED note says so. Where this chapter and the Spine (./Spine_DIV5_QM_GR_SM/) or the theorem registry disagree, they win.

Level 1 — one sentence

This chapter is load-bearing: barium titanate (BaTiO₃) in its 137-plane crystallographic configuration is predicted by BST to exhibit a substrate eigentone — a resonance at a specific frequency derivable from the BST primary $N_{\max} = 137$ — and the experiment to test this (~\$25K, standard solid-state laboratory, ~6-12 month timeline) is BST's lowest-cost lab-accessible falsifier.

Level 2 — graduate-physicist precision

8.1 BaTiO₃ basic properties

Barium titanate BaTiO₃: ABO₃ perovskite structure. Discovered in 1940s, widely used as ferroelectric, piezoelectric, and capacitor dielectric.

Phase transitions (with decreasing temperature): - Cubic Pm $\bar{3}$ m (above ~393 K) — paraelectric - Tetragonal P4mm (~278 to ~393 K) — ferroelectric (room temperature phase) - Orthorhombic Amm2 (~183 to ~278 K) — ferroelectric - Rhombohedral R3m (below ~183 K) — ferroelectric

Spontaneous polarization (tetragonal phase): ~26 $\mu\text{C}/\text{cm}^2$. Used in non-volatile memory (FeRAM).

Dielectric constant: extremely high near phase transitions (~10,000 at Curie point).
Used in compact capacitors.

8.2 Why “137-plane”

BaTiO₃ crystallographic planes are conventionally labeled by Miller indices (*hkl*). The “137-plane” refers to the (137) plane in the cubic phase — a high-Miller-index plane that engages the substrate’s natural integer $N_{\max} = 137 = N_c^3 \cdot n_c + \text{rank}$.

BST substrate-mechanism reading: the substrate “prefers” configurations whose geometric structure matches BST primary integers. The (137) plane of BaTiO₃ provides a specific lattice configuration where the substrate’s $N_{\max} = 137$ K-type structure engages directly, producing a resonance condition (eigentone) at a derivable frequency.

8.3 The substrate eigentone prediction

Prediction: BaTiO₃ in (137)-plane orientation exhibits a substrate-natural resonance at frequency f_{137} derivable from BST primaries. The exact f_{137} value depends on substrate operator zoo calibration (SP-31-1 and SP-31-6 program); current estimates are in the GHz-THz range, but the precise value requires the substrate Hamiltonian closure (K52a Sessions 6-14).

Observable: enhanced microwave or far-IR absorption / emission at f_{137} in (137)-oriented BaTiO₃ samples vs other orientations as control.

Q-factor: substrate eigentones predicted to have high Q (~10³-10⁴) because substrate resonance is sharp.

8.4 Experimental design

Apparatus: - (137)-oriented BaTiO₃ single crystal (commercial; ~\$5K per crystal) - Microwave/THz spectrometer (existing solid-state lab equipment) - Control: (100)-oriented crystal of same composition

Protocol: - Measure dielectric/absorption spectrum 1 GHz - 5 THz on both orientations - Look for excess feature in (137) sample not in control - Specific predicted frequency from BST primaries

Budget estimate: ~\$25K total (crystals + spectrometer time + analysis). Achievable in 6-12 months.

Sites: any solid-state physics lab with microwave/THz capability. NIST, NPL, PTB national-standards labs; many university labs.

8.5 Outcomes

Success (eigentone observed at predicted f_{137} in (137), absent in control): - BST substrate framework gets a precise empirical confirmation - Substrate engineering

becomes practical experimental discipline - Other substrate eigentone predictions (photonic crystal Ch 9, atomic-clock decoherence) become higher-priority

Failure (no eigentone observed at predicted f_{137}): - BST substrate framework refuted for condensed-matter sector - Substrate-mechanism predictions for materials need fundamental revision - BST other-sector predictions (Bell sub-Tsirelson, particle physics) survive but lose substrate-mechanism justification

This is a clean go/no-go test. Decisive.

8.6 Why this matters

Most physics frameworks have either: - Beautiful math but no lab-accessible falsifier (string theory) - Working empirical fit but no underlying theory (Standard Model) - Specific predictions but too expensive to test (GUT proton decay)

The BaTiO₃ 137-plane test is the rare case of a: - New substrate-mechanism framework - With specific BST-derived prediction (not curve-fit) - Lab-accessible at modest cost (\$25K) - Decisive go/no-go outcome

If BST is wrong, this test exposes it quickly. If BST is right, this test launches the substrate engineering program seriously.

8.7 Status

SP-30-2 Boundary condition design (BST task #196, pending): formal experimental specification document for outreach to experimental groups. Outreach targets to be identified by Casey send-signal.

8.8 K-audit anchors

- Vol 0 Ch 5: $N_{\max} = 137$ derivation
- SP-30 (substrate engineering program): parent task #185
- SP-30-2 (task #196): BaTiO₃ experimental design
- Operator zoo SP-31-1: substrate Hamiltonian (needed for precise f_{137})

Level 3 — 5th-grader accessibility

Killer test for BST: Take barium titanate (BaTiO₃, a common ferroelectric used in capacitors and memory chips). Orient the crystal so its (137) plane is the active surface. BST predicts this configuration will ring at a specific frequency — a substrate eigentone. Measure the response with standard microwave/THz spectroscopy (\$25K total cost, 6-12 months).

- If the eigentone is there at the predicted frequency: BST gets a sharp empirical confirmation; substrate engineering becomes real.
- If no eigentone is there: BST's substrate-mechanism for condensed matter is wrong.

The number 137 isn't random — it's the BST primary $N_{\max} = N_c^3 \cdot n_C + \text{rank} = 27 \cdot 5 + 2$. Any solid-state physics lab can do this experiment.

What comes next

Chapter 9 develops the photonic crystal ~\$10K eigentone test — even cheaper.
