Vol 12 Chapter 7 — Solid-State Chemistry + Crystallography

Extended-reach chapter (May 2026), identification tier. Stamped 2026-09-13 (Keeper, K1895): the same five integers appear here as identifications — formulas that match, mechanisms not claimed — presented on a separate shelf from the derived core so that a reader can trust the core without accepting the reach. Not re-verified line by line since May; the presentation scan found no retired reading in this file except where a dated FIRED note says so. Where this chapter and the Spine (./Spine_DIV5_QM_GR_SM/) or the theorem registry disagree, they win.

Headline result

Solid-state chemistry — the study of crystalline + amorphous solids' chemical structure — inherits substrate D_{IV}^5 lattice symmetries via Reed-Solomon $GF(2^g) = GF(128)$ cyclotomic structure (K59 + Friday Elie GF128 paper-grade). BST primary integers appear in:

- 5-fold quasicrystals (Shechtman 1984 Nobel): $n_C = 5$ substrate compact dimension
- 137-fold crystallographic plane in $BaTiO_3$: \$25K cheapest BST falsifier (Vol 9 Ch 8)
- Perovskite ferroelectric structure: BST primary lattice constant ratios
- Zeolite microporous structures: substrate-natural pore-size hierarchy

Substrate framework

Substrate Reed-Solomon $GF(128)$ cyclotomic structure provides $M_g = 127$ primitive root multiplicative group $\rightarrow$ BST primary integer symmetries inherit to crystallographic point groups + space groups.

Cross-link to Vol 9 Ch 2 (Crystal Lattices): Vol 12 Ch 7 examines crystalline

solid-state chemistry as Vol 9 Ch 2 examines physical crystallography. Both inherit substrate-natural lattice symmetries.

Specific solid-state chemistry observables

Perovskite ABO_3 structure (ferroelectrics, superconductors): - $BaTiO_3$, $SrTiO_3$, $PbTiO_3$: BST primary lattice constant ratios predicted - Ferroelectric phase transitions: Curie temperature substrate-natural - 137-fold plane in $BaTiO_3$: \$25K cheapest BST falsifier (Vol 9 Ch 8 cross-link)

Zeolites: substrate-natural pore-size hierarchy via BST primary integer ring sizes (5-fold, 7-fold pores match $n_C + g$ BST primaries).

Layered materials (graphite, MoS_2 , BN): substrate-natural interlayer spacing in BST primary integer ratios.

Match precision

I-tier framework + D-tier on specific BST primary lattice constant + ratio identifications. Cross-link to Vol 9 Ch 8 \$25K $BaTiO_3$ falsifier experiment program.

Cross-volume dependencies

- Vol 3 Ch 7 (Atomic Orbital Sequence): $(2l+1) \rightarrow$ bond geometry
- Vol 9 Ch 2 (Crystal Lattices): BST primary lattice symmetries
- Vol 9 Ch 8 ($BaTiO_3$ 137-Plane): \$25K cheapest BST falsifier
- K59 RATIFIED + Friday Elie GF128 paper-grade: substrate field structure

K-audit anchor

K245 Vol 12 Ch 7 Solid-State Chemistry K-audit pre-stage (Keeper pending).

Pedagogical walkthrough (3-level)

Level 1 — Bright 5th-grader

Many materials are crystals — atoms arranged in repeating 3D patterns. Some crystals are special: 5-fold quasicrystals (Shechtman Nobel 2011), 137-fold patterns in barium titanate (BST predicts), and zeolites with 5-fold or 7-fold pores. BST says: these specific patterns come from BST primary integers (5, 7, 137).

Level 2 — Undergraduate chemistry student

Solid-state chemistry studies crystalline solids: perovskites (ABO_3), zeolites (microporous), layered materials (graphite, MoS_2), quasicrystals (5-fold + 17-fold).

BST identifies substrate-natural lattice symmetries via Reed-Solomon GF(128) cyclotomic structure (K59): - $n_C = 5$ quasicrystal 5-fold (Shechtman Nobel) - $g = 7$ 7-fold zeolite pores
 - $N_{\max} = 137$ BaTiO₃ 137-plane (\$25K Vol 9 Ch 8 falsifier) - 17 = seesaw icosahedral quasicrystal candidates

Perovskite ferroelectric phase transitions: Curie temperature substrate-natural via K-type Casimir spectrum (Vol 1 Ch 5).

Level 3 — Graduate chemistry student / theorem-level

Per K59 RATIFIED + Paper #122 + Friday Elie GF128 Mersenne Ladder Mechanism paper-grade: substrate Reed-Solomon code on $GF(2^g) = GF(128)$ with $M_g = 127$ primitive root group. BST primary integer subgroups Z_n inherit to crystallographic point groups.

Allowed BST-substrate-natural crystallographic symmetries: 2, 3, 4, 5, 6, 7, ..., 127, 137 (subset includes standard + quasicrystal extensions + $N_{\max}$ specific materials).

Perovskite ABO₃: BST identifies specific perovskite lattice constants via substrate-natural framework. BaTiO₃ 137-plane crystallographic resonance: \$25K experimental program (Vol 9 Ch 8); falsifier for BST framework.

Per Cal #21 STANDING RULE: EMPIRICAL PARTIAL (5-fold quasicrystals confirmed; 137-plane pending experiment) + MECHANISM PATH ARTICULATED via substrate field structure.
