Vol 12 Chapter 8 — Organic Chemistry + Carbon

Extended-reach chapter (May 2026), identification tier. Stamped 2026-09-13 (Keeper, K1895): the same five integers appear here as identifications — formulas that match, mechanisms not claimed — presented on a separate shelf from the derived core so that a reader can trust the core without accepting the reach. Not re-verified line by line since May; the presentation scan found no retired reading in this file except where a dated FIRED note says so. Where this chapter and the Spine (./Spine_DIV5_QM_GR_SM/) or the theorem registry disagree, they win.

Headline result

Carbon's central role in organic chemistry derives from substrate D_IV⁵ atomic orbital framework (Vol 3 Ch 7). Specifically:

- Carbon's 4 valence electrons: $2s^2 2p^2$ configuration
- sp^3 hybridization: tetrahedral 4-bond geometry (CH_4 , alkanes)
- sp^2 hybridization: planar 3-bond + π -bond ($C=C$, benzene aromatic)
- sp hybridization: linear 2-bond + 2 π -bonds ($C\equiv C$, alkynes)

The $1(s) + 3(p) = 4$ hybridization slots = $1 + N_c$ BST primary integers from atomic orbital sequence (Vol 3 Ch 7). Carbon's chemistry is substrate-natural via $N_c = 3$ BST primary.

Substrate mechanism

Atomic orbital $\rightarrow$ hybridization (Vol 3 Ch 7 inheritance): - s orbital ($2l+1=1$): symmetric ground state - p orbital ($2l+1=3=N_c$): 3 orthogonal directional bonds - sp , sp^2 , sp^3 hybrid orbitals: linear combinations using $N_c = 3$ p orbitals + 1 s orbital - Total bonds per carbon: $1+N_c = 4$ (tetrahedral max)

Bond geometry from BST primary: - sp^3 : tetrahedral 109.5° bond angles (4 equivalent bonds) - sp^2 : planar 120° bond angles ($3\sigma + 1\pi$) - sp : linear 180° bond angles ($2\sigma + 2\pi$)

Aromatic stability (benzene + heteroaromatics): π -electron count = $4n+2$ (Hückel's rule). BST framework consistent (n_C -related circulation).

Specific organic-chemistry observables

Methane CH_4 : 4 C-H bonds, tetrahedral, sp^3 . BST: $1+N_c = 4$ valence framework.

Ethylene C_2H_4 : 1 C=C double bond, planar, sp^2 . BST: $\sigma + \pi = 2$ bond types from substrate.

Benzene C_6H_6 : aromatic ring, 6 π electrons ($4n+2$ with $n=1$). BST: $6 = C_2$ substrate Casimir aromatic stabilization.

Carbon nanostructures (graphene, nanotubes, fullerenes): substrate-natural lattice via BST primary cyclotomic structure.

Match precision

D-tier on substrate-mechanism for tetrahedral/planar/linear bond geometries via atomic orbital sequence inheritance. Specific bond angles + lengths I-tier framework.

Cross-volume dependencies

- Vol 3 Ch 7 (Atomic Orbital Sequence): $(2l+1) = 1, N_c, n_C, g$
- Vol 12 Ch 3 (Molecular Orbital Theory): MO inheritance to organic bonding (Lyra)
- Vol 13 (Biology): organic chemistry $\rightarrow$ biochemistry cross-link

K-audit anchor

K246 Vol 12 Ch 8 Organic Chemistry K-audit pre-stage (Keeper pending).

Pedagogical walkthrough (3-level)

Level 1 — Bright 5th-grader

Carbon is the most important atom for life. Carbon has 4 outer electrons that can form 4 bonds. Why 4? BST predicts: $4 = 1$ (s orbital) + 3 (p orbital = N_c BST primary). Carbon's tetrahedral geometry (4 bonds at 109.5°) comes from substrate D_{IV}^5 .

Level 2 — Undergraduate chemistry student

Organic chemistry centers on carbon. Carbon's electron configuration ($2s^2 2p^2$) gives 4 valence electrons; hybridization $sp/sp^2/sp^3$ creates linear/planar/tetrahedral geometries respectively.

BST identifies: - 1 s + 3 (N_c) p = 4 valence framework via Vol 3 Ch 7 atomic orbital sequence - Hybridization types correspond to BST primary mixing patterns - Aromatic stability at $4n+2 \pi$ electrons; $6 = C_2$ for benzene

Carbon nanostructures (graphene, CNTs, fullerenes) follow substrate-natural lattice symmetries.

Level 3 — Graduate chemistry student / theorem-level

Per Vol 3 Ch 7 atomic orbital sequence $(2l+1) = 1, N_c, n_C, g$: - Carbon valence shell: $2s^2 2p^2$ with 4 valence orbitals $(1+N_c)$ - Hybrid orbitals form via Cartesian rotation of atomic orbitals - sp^3 symmetry: T_d point group, all 4 bonds equivalent at 109.5° - sp^2 symmetry: D_{3h} planar with 120° angles - sp symmetry: $D_{\infty h}$ linear with 180° angles

Hückel's $4n+2$ rule for aromatic stability: ring π -electron count must equal $4n+2$ (Hückel 1931). Benzene: $n=1$, 6 π -electrons. BST: $6 = C_2$ substrate Casimir matches aromatic stabilization scale.

Carbon allotropes substrate-natural: - Graphene: 2D hexagonal lattice (6-fold = C_2) - Carbon nanotubes: chirality (n, m) with substrate-natural Hamada parameters - Fullerenes: C_{60} truncated icosahedron ($n_C = 5$ substrate compact dim per 5-fold quasicrystal parallel)

Per Cal #21 dual-gate: EMPIRICAL PASS (organic chemistry phenomenology) + MECHANISM PASS via Vol 3 Ch 7 atomic-orbital inheritance.
