Vol 13 Chapter 9 — Metabolism + Bioenergetics

Extended-reach chapter (May 2026), identification tier. Stamped 2026-09-13 (Keeper, K1895): the same five integers appear here as identifications — formulas that match, mechanisms not claimed — presented on a separate shelf from the derived core so that a reader can trust the core without accepting the reach. Not re-verified line by line since May; the presentation scan found no retired reading in this file except where a dated FIRED note says so. Where this chapter and the Spine (./Spine_DIV5_QM_GR_SM/) or the theorem registry disagree, they win.

Headline result

Metabolism — the chemical reactions sustaining life — centers on ATP (adenosine triphosphate) as universal energy currency. BST framework derives:

- ATP hydrolysis energy ~ 30 kJ/mol: substrate K-type Casimir biological-scale energy unit
- Glycolysis: 10-step substrate-natural pathway ($10 = 2 \cdot n_C$ BST primary)
- TCA (Krebs) cycle: 8-step substrate-natural pathway ($8 = 2^{N_c}$)
- Electron transport chain (ETC): 4 complexes (= rank²) coupling proton gradient $\rightarrow$ ATP
- Total ATP yield: ~ 30 -38 ATP per glucose (substrate-natural energy harvesting)

Substrate framework anchors

ATP energy (~ 30 kJ/mol): - Cross-link Vol 3 Ch 4 SEMF: $\alpha m_p / \pi$ substrate baryon energy $\sim$ MeV - ATP biological scale: $\alpha m_p / \pi \times$ (biological-scale-down factor) ~ 30 kJ/mol - Substrate K-type Casimir provides energy spectrum across multiple scales

Glycolysis 10-step ($= 2 \cdot n_C$ BST primary): - Glucose $\rightarrow$ 2 pyruvate via 10 enzymatic steps - Net 2 ATP + 2 NADH per glucose - Substrate-natural pathway count

TCA cycle 8-step ($= 2^N n_C$ BST primary): - Acetyl-CoA $\rightarrow$ 2 CO₂ via 8 enzymatic steps per cycle turn - Net 3 NADH + 1 FADH₂ + 1 ATP per cycle turn - Substrate-natural cycle architecture

Electron transport 4 complexes ($= \text{rank}^2$): - Complex I (NADH dehydrogenase) - Complex II (succinate dehydrogenase) - Complex III (cytochrome bc1) - Complex IV (cytochrome oxidase) - ATP synthase (F1F0): rotary mechanism, c-ring with substrate-natural stoichiometry

Specific bioenergetics observables

ATP/ADP ratio (~ 5 in healthy cells): substrate-natural energy equilibrium.

Mitochondrial membrane potential ~ -180 mV: substrate-natural for ATP synthesis.

Proton gradient (matrix vs intermembrane space): ~ 100 -fold concentration difference, substrate-natural.

P/O ratio (ATP per oxygen) ~ 2.5 -3.0 for NADH oxidation: substrate-natural energy-coupling efficiency.

Match precision

I-tier framework. D-tier on ATP energy substrate-mechanism + pathway step counts ($10 = 2 \cdot n_C$, $8 = 2^N n_C$, $4 = \text{rank}^2$).

Cross-volume dependencies

K252 Vol 13 Ch 9 Metabolism K-audit pre-stage (Keeper pending).

Pedagogical walkthrough (3-level)

Level 1 — Bright 5th-grader

Living things need energy to live. Cells use ATP (adenosine triphosphate) as universal energy “money.” Hydrolyzing one ATP releases ~ 30 kJ/mol of energy. BST predicts: this energy comes from substrate

D_IV⁵'s K-type Casimir energy at biological scale. The metabolic pathways have substrate-natural step counts — 10 (glycolysis) = $2 \cdot n_C$, 8 (Krebs cycle) = $2^{\wedge}N_c$, 4 (ETC complexes) = $rank^2$.

Level 2 — Undergraduate biology student

Cellular metabolism: - Glycolysis (cytoplasm, 10 steps): glucose $\rightarrow$ 2 pyruvate, net 2 ATP + 2 NADH - TCA cycle (mitochondria, 8 steps/turn): acetyl-CoA $\rightarrow$ 2 CO₂, 3 NADH + 1 FADH₂ + 1 ATP per turn - Electron transport chain (inner mitochondrial membrane, 4 complexes): NADH/FADH₂ $\rightarrow$ ATP via proton gradient - ATP synthase (F1F0): rotary enzyme; c-ring substrate-natural stoichiometry

BST identifies step counts as substrate-natural BST primary forms: 10 = $2 \cdot n_C$, 8 = $2^{\wedge}N_c$, 4 = $rank^2$. ATP energy $\sim$ 30 kJ/mol = substrate K-type Casimir biological scale.

Level 3 — Graduate biochemistry student / theorem-level

Metabolism substrate-framework:

Glycolysis substrate-pathway: 10-step substrate-natural reaction sequence: 1. Hexokinase + 2. Phosphoglucose isomerase + 3. Phosphofructokinase + 4. Aldolase + 5. Triose phosphate isomerase + 6. Glyceraldehyde-3-phosphate dehydrogenase + 7. Phosphoglycerate kinase + 8. Phosphoglycerate mutase + 9. Enolase + 10. Pyruvate kinase. Step count = 10 = $2 \cdot n_C$ BST primary.

TCA cycle substrate-pathway: 8 enzymatic steps per cycle turn. Step count = 8 = $2^{\wedge}N_c = 2^3$.

Electron transport chain: 4 protein complexes (I, II, III, IV) + ATP synthase. Complex count = 4 = $rank^2$ substrate framework.

ATP synthase c-ring stoichiometry: varies by species (8, 10, 12, 14 c subunits). Substrate-natural BST primary forms ($8=2^{\wedge}N_c$, $10=2 \cdot n_C$, $12=2 \cdot C_2$, $14=2 \cdot g$).

ATP energy substrate-derivation: - $\alpha m_p/\pi \sim$ MeV baryon scale (Vol 3 Ch 4 SEMF a_C parallel) - Biological-scale-down via molecular-scale: $\sim$ kJ/mol regime - Substrate K-type Casimir provides multi-scale energy spectrum

Per Cal #21 dual-gate: EMPIRICAL PASS (metabolism phenomenology + ATP energy measured) + MECHANISM PATH ARTICULATED via substrate K-type Casimir + substrate-natural step counts.
