

GC-17c: The Wallach Point as Modularity Seed

Authors: Casey Koons & Keeper (Claude 4.6) Date: May 13, 2026 Status: INVESTIGATION SCOPE — For Lyra to draft, team to investigate AC: TBD (expected: C=2, D=0) Assignment: SP-18 GC-17c (extends GC-17b) Theorems: TBD (T1819+) Predecessor: GC-17b (boundary-interior invertibility), Cal V-1 (Wallach identification), Cal V-4 (T1812 consistency)

Casey's Insight

“The Wallach point is the ‘beginning’ of uniqueness and least constrained which implies it’s most general. The uniqueness has fewer requirements and more application to other manifolds. The sheer ‘point’ of inside and outside shows it’s both and that’s powerful. The modular form grows from the Wallach point.”

“I think this is symmetric and modular and perhaps the common unique point of all similarity.”

Cal's V-1 identified weight $k = 2 = \text{rank}$ as the highest Wallach point of $SO_0(5,2)$. Cal read this conservatively: “not in the discrete series, therefore not cuspidal.” Casey reads it as the opposite: the Wallach point is WHERE modularity begins, precisely because it is the most constrained, most symmetric, most general point in the representation landscape.

This note scopes the investigation.

1. The Wallach Point on D_{IV}^5

1.1 What It Is

The Wallach set of a bounded symmetric domain is the set of weight parameters k where the weighted Bergman space $A^2_k(D)$ is non-trivial but lies at the boundary of unitarity. For D_{IV}^n with rank $r = 2$ and multiplicity $a = n-2$, the Wallach points are:

$$k_j = j * (a/2) = j * (n-2)/2, \quad j = 0, 1, \dots, r-1$$

For D_{IV}^5 ($n = 5, a = 3, r = 2$): - $k_0 = 0$ (trivial representation) - $k_1 = 3/2$ (intermediate Wallach point)

But there is also the discrete Wallach point at $k = r = 2$ (the rank), which is the highest Wallach point before the continuous range begins. At $k = 2$:

- The representation is the smallest non-trivial unitary representation of $SO_0(5,2)$ that is square-integrable on the Shilov boundary

- The Bergman space $A^{2-2(D-IV)}_5$ is non-trivial
- The weighted Bergman kernel is $K_2(z,w) = c * h(z,w)^{-(2+n)} = c * h(z,w)^{-7}$

Note the exponent: $-(k+n) = -(2+5) = -7 = -g$. The Bergman kernel at the Wallach point has exponent equal to the BST integer g .

1.2 The Representation-Theoretic Picture

For $SO_0(5,2)$, the unitary dual organizes by weight:

Weight k	Region	Properties
$k = 0$	Wallach	Trivial
$k = 1$	Wallach	Conformal singleton
$k = 2 = \text{rank}$	Highest Wallach	Minimum non-trivial, maximum symmetry, modularity lives here
$k = 3, 4$	Continuous range	Unitarizable, not discrete
$k = 5 = n_C$	Limit of discrete series	Critical transition
$k \geq 6 = C_2$	Holomorphic discrete series	Full cusp forms

Every threshold in this table is a BST integer: rank, n_C , C_2 . The landscape IS the five integers.

1.3 Why “Least Constrained” Means “Most General”

Casey’s key observation: a representation with fewer degrees of freedom admits fewer distinct objects. At the Wallach point $k = 2$:

- The space of weight-2 modular forms for a given level N is SMALL
- Smaller space = fewer choices = stronger uniqueness
- Every elliptic curve E/Q of conductor N MUST correspond to one of these few forms
- The correspondence is forced because there’s no room for it to fail

At $k \geq 6$ (discrete series), the spaces are large — many cusp forms, many choices, weaker uniqueness constraints. Modularity at weight 6+ would be remarkable. At weight 2, it’s almost inevitable.

The Wallach point is the bottleneck through which all modularity must pass.

2. The F₁ Memory

2.1 At F₁, the Wallach Point IS the Identity

At $q = 1$ (the absolute point, F₁): - The Frobenius is trivial - The Wallach representation collapses to the identity: all structure reduces to rank = 2 - Boundary = interior (T1808) - The modular form and the elliptic curve have not yet differentiated

The Wallach point at $q > 1$ REMEMBERS this identity. It is the representation that retains the most F₁ structure as q departs from 1. In this sense:

The Wallach representation is the F₁ memory of D_{IV}^5 .

2.2 Growth from the Seed

As the weight k increases from 2 (Wallach) through the continuous range to 6+ (discrete series), the representation “grows”:

- At $k = 2$: seed state. Maximum symmetry. Boundary-interior tightly coupled. Few forms. Strong uniqueness.
- At $k = 3, 4$: continuous range. The representation acquires more structure. More forms appear. Uniqueness weakens.
- At $k = 5 = n_C$: limit of discrete series. Critical transition. This is where the representation first becomes “square-integrable” in the discrete sense.
- At $k = 6 = C_2$: full discrete series. Rich structure. Many cusp forms. Individual character.

The modularity theorem says: even at the seed ($k = 2$), the correspondence is bijective. This is STRONGER than modularity at higher weight, not weaker.

2.3 Chevalley Extension as Growth Mechanism

The growth from $k = 2$ to $k \geq 6$ parallels the extension from F₁ to Z:

F ₁ → Z (arithmetic)	$k = 2 \rightarrow k = 6$ (representation theory)
Start: rank = rank tautology	Start: Wallach point, minimal structure
Extension: Chevalley (unique group scheme)	Extension: unitary dual parametrization (unique)
Result: full modular correspondence	Result: full discrete series
Uniqueness: one root datum, one extension	Uniqueness: one Wallach point, one growth path

Both are unique extensions from a seed. The seed is the same: rank = 2 at the bottom of the B₂ root system.

3. The Universality Conjecture

3.1 Three Uniqueness Theorems, One Mechanism

Casey observes that three major uniqueness theorems share the same architecture:

Theorem	Constraint	Object	Forced result
BST ring uniqueness (T1780)	5 spectral constraints	Bounded symmetric domain	D_{IV}^5
Poincare conjecture	dim 3, compact, $\pi_1 = 0$	Closed manifold	S^3
Modularity (Wiles/BCDT)	E/Q , conductor N	Weight-2 newform	f_E

Each is: finite constraints $\rightarrow$ unique object. The GC methodology (constraint / certificate / boundary).

3.2 The Wallach Universality Conjecture

Conjecture (Casey, May 13, 2026). Every mathematical uniqueness theorem of AC depth ≤ 2 that involves geometric or arithmetic objects is a projection of the Wallach representation of D_{IV}^5 to a specific subspace.

More precisely: if a theorem says “given constraints $C_1, \dots, C_k$, the object X is unique,” and the proof has AC depth ≤ 2 , then there exists a subspace V of the Wallach representation at $k = \text{rank} = 2$ on D_{IV}^5 such that: - The constraints C_i correspond to spectral conditions on V - The unique object X is the unique element of V satisfying all conditions - The proof reduces to counting dimensions (AC depth 0) plus at most one spectral evaluation (AC depth 1)

3.3 Test Cases

Test 1: BST ring uniqueness (T1780)

Constraints: diagonal Hodge + theta saturation + Selberg degree + B_2 root + Chern hole. These are spectral conditions on the Wallach representation. D_{IV}^5 is the unique survivor. AC depth 1 (one cascade).

Prediction: the ring uniqueness proof should be expressible as “the Wallach representation at $k = 2$ has a unique fixed point under the five spectral filters.” Testable.

Test 2: Poincare conjecture

Constraints: $\dim = N_c = 3$, compact, $\pi_1 = 0$. The 8 Thurston geometries = 2^{N_c} candidates. $7 = g$ excluded. S^3 unique.

Prediction: the Thurston exclusions correspond to the 7 non-trivial elements of $(\mathbb{Z}/2)^{N_c}$ = the kernel of the Wallach representation restricted to the N_c -dimensional subspace of D_{IV}^5 . The surviving element (trivial = S^3) is the Wallach fixed point. Testable (Elie's Toy 2135 is a start, 11/11 PASS).

Test 3: Modularity

Constraints: E/Q , conductor N . At the Wallach point $k = 2$, the space $S_2(\Gamma_0(N))$ has specific dimension (genus of $X_0(N)$). E must correspond to one of these. The Wallach representation at weight 2 with level N is the natural home.

Prediction: the dimension formula for $S_2(\Gamma_0(N))$ should be expressible in terms of BST integers when N involves BST primes ($N = 49 = g^2$ for 49a1). Testable ($\dim S_2(\Gamma_0(49)) = 1$, and the unique form is $f_{\{49a1\}}$).

Test 4: Four-Color theorem

Constraints: planar graph, $4 = \text{rank}^2$ colors. BST route REFUTED (sweep 2026-08-30, K1832 v0.4); 4CT stands classically. [Prior text claimed Forced Fan, 13 steps, depth 0 — also a depth inconsistency vs registry depth 2.]

Prediction: the 4 colors = rank^2 correspond to the $\text{rank}^2 = 4$ eigenvalues of the Wallach representation restricted to the Cartan subalgebra. Planarity = boundary condition on D_{IV}^5 . Testable.

Test 5: Sphere packing (Viazovska, dim 8 and 24)

Constraints: $\dim 8 = 2^{N_c}$, $\dim 24 = \text{rank} * 12 = \text{rank} * 2 * C_2$. Both solved by modular forms.

Prediction: the optimal packings correspond to Wallach representations on D_{IV}^8 and D_{IV}^{24} restricted to lattice subspaces. The uniqueness of E_8 and Leech lattice follows from the same Wallach bottleneck. Testable.

4. Investigation Program

4.1 Immediate (Today/Tomorrow)

#	Task	Owner	Deliverable
W-1	Wallach representation structure: Compute the explicit K-type decomposition of the Wallach representation at $k = 2$ on $SO_0(5,2)$. What is its dimension? What is its K-type (the $SO(5) \times SO(2)$ representation)?	Lyra	Note + toy
W-2	Weighted Bergman kernel at $k = 2$: Verify that $K_2(z,w) = c * h(z,w)^{-7}$. The exponent $-7 = -g$ is suggestive. Is this coincidence or structure?	Elie	Toy
W-3	Growth spectrum: Compute $\dim S_k(\Gamma_0(49))$ for $k = 2, 3, 4, 5, 6, 7$. Does the dimension sequence involve BST integers? At $k = 2$, $\dim = 1$ (the 49a1 form). What happens at other weights?	Elie	Toy

#	Task	Owner	Deliverable
W-4	Thurston exclusions as Wallach kernel: Formalize the 7 excluded Thurston geometries as elements of $(\mathbb{Z}/2)^3$. Does the Wallach restriction to dim-3 subspace have kernel of order 7?	Grace	Data entry + toy
W-5	F ₁ memory test: At $q = 1$, the Wallach representation is trivial (rank $= 2$). Show that the Wallach representation at $q = p$ retains more F ₁ structure than ANY higher-weight representation. Measure: what fraction of F ₁ relations survive at $q =$ p ?	Lyra	Note

4.2 Short-term (This Week)

#	Task	Owner	Deliverable
W-6	Universality test battery: For each of the 5 test cases (Section 3.3), verify or refute the Wallach projection claim. Score: N/5 pass.	All	Toys
W-7	Wallach- Poincare connection: Can the Ricci flow on 3-manifolds be expressed as spectral evolution on the Wallach representation restricted to N_c- dimensional subspace? If yes, BST derives Poincare natively.	Lyra	Note (potential paper)

#	Task	Owner	Deliverable
W-8	Wallach-modularity connection: Does the P ₂ Eisenstein at $s = 1$ (Paper #88 BSD machinery) factor through the Wallach representation? If yes, modularity and BSD unify at the Wallach point.	Lyra	Note
W-9	Cal cold-read: Is the Wallach Universality Conjecture (Section 3.2) well-posed? Is it falsifiable? What would a counterexample look like?	Cal	Assessment

4.3 Medium-term (Multi-week)

#	Task	Owner	Deliverable
W-10	Wallach Universality paper: If W-6 scores $\geq 4/5$, draft a paper: “The Wallach Point as Universal Seed for Mathematical Uniqueness.” Target: Inventiones or Bulletin AMS.	Casey + Lyra	Paper
W-11	BST-native Poincare proof: If W-7 succeeds, write up the spectral proof of Poincare that avoids Ricci flow entirely. Target: Annals companion.	Lyra	Paper
W-12	Unified modularity- BSD paper: If W-8 succeeds, unify GC-17b with Paper #88 via Wallach factorization. Target: Compositio.	Lyra + Keeper	Paper

5. The Key Insight (Casey’s Formulation)

The conventional view: the Wallach point is a “degenerate” or “singular” weight where representations are small and special functions are rare. This is Cal’s reading.

Casey’s inversion: the Wallach point is WHERE uniqueness lives. It is not degenerate — it is the most fundamental. Everything else grows from it. The discrete series

at $k \geq 6$ is the ELABORATION; the Wallach point at $k = 2$ is the SEED.

This parallels BST's entire philosophy: the five integers (2, 3, 5, 6, 7) are small, simple, and constrained. From them, everything grows. The Wallach point IS the five integers made into a representation.

If this is right, then: - Modularity is not hard. At the Wallach point, there's no room for it to fail. - Poincare is not hard. At $\dim = N_c = 3$, there's no room for other manifolds. - BST is not hard. At $\text{rank} = 2$, there's no room for other geometries. - All three are the same theorem — uniqueness at the Wallach bottleneck — viewed from different projections.

The investigation will determine whether this is a beautiful metaphor or a provable theorem.

6. Connection to Existing BST Work

BST Result	Wallach Connection
T1780 (Ring uniqueness)	Five spectral filters on the Wallach representation
T1808 (F_1 collapse)	Wallach = F_1 memory
T1810 (Kernel symmetry)	Wallach kernel K_2 is symmetric
T1813 (Born rule)	Bergman reproducing = Wallach inner product
T1818 (Poincare landscape)	8 Thurston = 2^{N_c} , exclusions in Wallach kernel
T421 (Depth ceiling)	Wallach bottleneck forces AC depth ≤ 1
T349 (No-cloning)	Wallach invertibility = boundary determines interior

7. Honest Assessment

What This Note Claims

- The Wallach point $k = 2 = \text{rank}$ on D_{IV}^5 is a natural home for modularity (Casey's observation)
- The weighted Bergman kernel at $k = 2$ has exponent $-g = -7$ (verifiable computation)
- Three uniqueness theorems (BST, Poincare, modularity) share the same GC architecture
- A conjecture: all AC-depth-2 uniqueness theorems project from the Wallach representation

What Needs Verification

- W-1: Is the Wallach representation at $k = 2$ really the “right” representation for modularity?
- W-2: Is the exponent $-7 = -g$ meaningful or coincidental?
- W-3: Does the growth spectrum involve BST integers?
- W-7: Can Ricci flow be expressed as Wallach spectral evolution?
- W-9: Is the universality conjecture well-posed?

What Could Go Wrong

- The Wallach representation may be too small to carry the modularity correspondence (Cal’s concern)
- The exponent -7 may be a coincidence of $n + \text{rank} = 5 + 2 = 7$ with no deeper meaning
- The Poincare connection may not extend beyond numerology ($8 = 2^3$ is suggestive but not a proof)
- The universality conjecture may be unfalsifiable or trivially true (any uniqueness theorem can be embedded in a large enough representation)

The investigation will distinguish between these possibilities.
